Project Five

Implementing Active Directory Domain Services And Joining A Domain

Instructor : Dr. Mark Llewellyn

Email: markl@cs.ucf.edu

Office: HEC 236, 407-823-2790

Office Hours: M&W 1:00-3:00pm, T&Th 10:30am-12:30pm

Department of Electrical Engineering and Computer Science
Computer Science Division
University of Central Florida

Project Five

- **Title:** “Project Five: Implementing Active Directory Domain Services And Joining A Domain”
- **Points:** 50 points
- **Due Date:** March 25, 2015 by 11:59 pm WebCourses time.
- **Objectives:** The completion of Project Four left you with a virtual network of three machines, named Mark-Server1, Mark-Mark-Server2, and Mark-Mark-Client1. For our savn.local network we will make Mark-Server1 the domain controller. This project will implement the Active Directory Domain Services on this server by configuring its server roles and join the two other VMs to the virtual network.
- **Deliverables:** Six screen shots as shown on pages 35, 36, 39, 51, 63, and 64. Make sure your server name shows in the screen shots.

Project Five – Background

- Active Directory Domain Services provides a directory service that you can use for centralized secure management of your network.
- Installing ADDS on Mark-Server1 will establish that server as the domain controller for the network that you constructed in Project Four.
- Be sure that you've successfully verified the IP connectivity of all three VMs and your host computer before you begin this project. You should have done this in Project Four, but it never hurts to recheck.
- What you'll be doing in this project is installing ADDS on Mark-Server1 and configuring its server roles as a domain controller. Following this you will join Mark-Server2 and Mark-Client1 to the domain now controlled by Mark-Server1.

Project Five – Background

- The next several pages will step you through the process of installing ADDS on Mark-Server1 and configuring its server role as the domain controller.
- Note that Mark-Server1 must be running in order to install ADDS and configure its server roles. The other VMs do not need to be running for this first part.

Installing ADDS In Mark-Server1

- To begin the process. Start Mark-Server1 and bring up the Server Manager. If you don't have this coming up automatically for your server, Click the Administrative Tools link from the Start menu and then click Server Manager.
- Scroll down the window until you find the Roles Summary sub-window.
- Hopefully by now you are quite familiar with these steps to find the roles a server is performing.
- See next page.

Installing ADDS In Mark-Server1

- In the Roles Summary area, click Add Roles.
- You'll most likely see a "Before You Begin" screen. As a future system administrator, you should read the information on this screen so that you are aware of the impact of changing a server's roles. (See next page for screen shot.)
- If the "Before You Begin" screen appeared, click Next. Otherwise select Server Roles from the menu on the left side of the screen. Either way you should now see the screen that appears on page 9.

Mark - Server 1 - VMware Player File Virtual Machine Help

Add Roles Wizard

Before You Begin

This wizard helps you install roles on this server. You determine which roles to install based on the tasks you want this server to perform, such as sharing documents or hosting a Web site.

Before you continue, verify that:

- The Administrator account has a strong password
- Network settings, such as static IP addresses, are configured
- The latest security updates from Windows Update are installed

If you have to complete any of the preceding steps, cancel the wizard, complete the steps, and then run the wizard again.

To continue, click Next.

Introduction to Active Directory Domain Services

Active Directory Domain Services (AD DS) stores information about users, computers, and other devices on the network. AD DS helps administrators securely manage this information and facilitates resource sharing and collaboration between users. AD DS is also required for directory-enabled applications such as Microsoft Exchange Server and for other Windows Server technologies such as Group Policy.

Things to Note

- To help ensure that users can still log on to the network in the case of a server outage, install a minimum of two domain controllers for a domain.
- AD DS requires a DNS server to be installed on the network. If you do not have a DNS server installed, you will be prompted to install the DNS Server role on this server.
- After you install the AD DS role, use the Active Directory Domain Services Installation Wizard (dcpromo.exe) to make the server a fully functional domain controller.
- Installing AD DS will also install the DFS Namespaces, DFS Replication, and File Replication services which are required by Directory Service.

Operating System Compatibility

Improved security settings in Windows Server 2008 affect older versions of Windows

Warning Windows Server 2008 domain controllers have a new more secure default for the security setting named "Allow cryptography algorithms compatible with Windows NT 4.0." This setting prevents Microsoft Windows and non-Microsoft SMB "clients" from using weaker NT 4.0 style cryptography algorithms when establishing security channel sessions against Windows Server 2008 domain controllers. As a result of this new default, operations or applications that require a security channel serviced by Windows Server 2008 domain controllers might fail.

Platforms impacted by this change include Windows NT 4.0, as well as non-Microsoft SMB "clients" and network-attached storage (NAS) devices that do not support stronger cryptography algorithms. Some operations on clients running versions of Windows earlier than Vista with Service Pack 1 are also impacted, including domain join operations performed by the Active Directory Migration Tool or Windows Deployment Services.

For more information about this setting, see Knowledge Base article 942564 (<http://go.microsoft.com/fwlink/?LinkId=104751>).

Installing ADDS In Mark-Server1

- Recall from our earlier discussions about Active Directory that domain controllers can run different versions of Windows Server operating systems.
- The ADDS functional level of a domain or forest depends on which versions of Windows Server operating systems you run on the domain controllers in the domain or forest.
- The domain or forest's advanced features are related to its functional level.
- See Active Directory – Part 2 pages 9 and 10 for more details.

Installing ADDS In Mark-Server1

- In our case, we will set the highest functional level, which is Windows Server 2008, since all of our virtual servers are running Windows Server 2008 and we do not have any servers running an older version of the operating system.

Mark - Server 1 - VMware Player File Virtual Machine Help

Server Manager

Active Directory Domain Services Installation Wizard

Set Forest Functional Level
Select the forest functional level.

Forest functional level:
Windows Server 2008

Details:
This forest functional level does not provide any new features over the Windows 2003 forest functional level. However, it ensures that any new domains created in this forest will automatically operate at the Windows Server 2008 domain functional level, which does provide unique features.

 You will be able to add only domain controllers that are running Windows Server 2008 or later to this forest.

Additional Domain Controller Options

Select additional options for this domain controller.

- ☒ DNS server
- ☒ Global catalog
- ☐ Read-only domain controller (RODC)

Additional information:

The first domain controller in a forest must not be an RODC.

We recommend that you install the DNS S controller.

More about [additional domain controller options](#)

Active Directory Domain Services Installation Wizard

 A delegation for this DNS server cannot be created because the authoritative parent zone cannot be found or it does not run Windows DNS server. If you are integrating with an existing DNS infrastructure, you should manually create a delegation to this DNS server in the parent zone to ensure reliable name resolution from outside the domain savn.local. Otherwise, no action is required.

Project Five – Joining The Domain

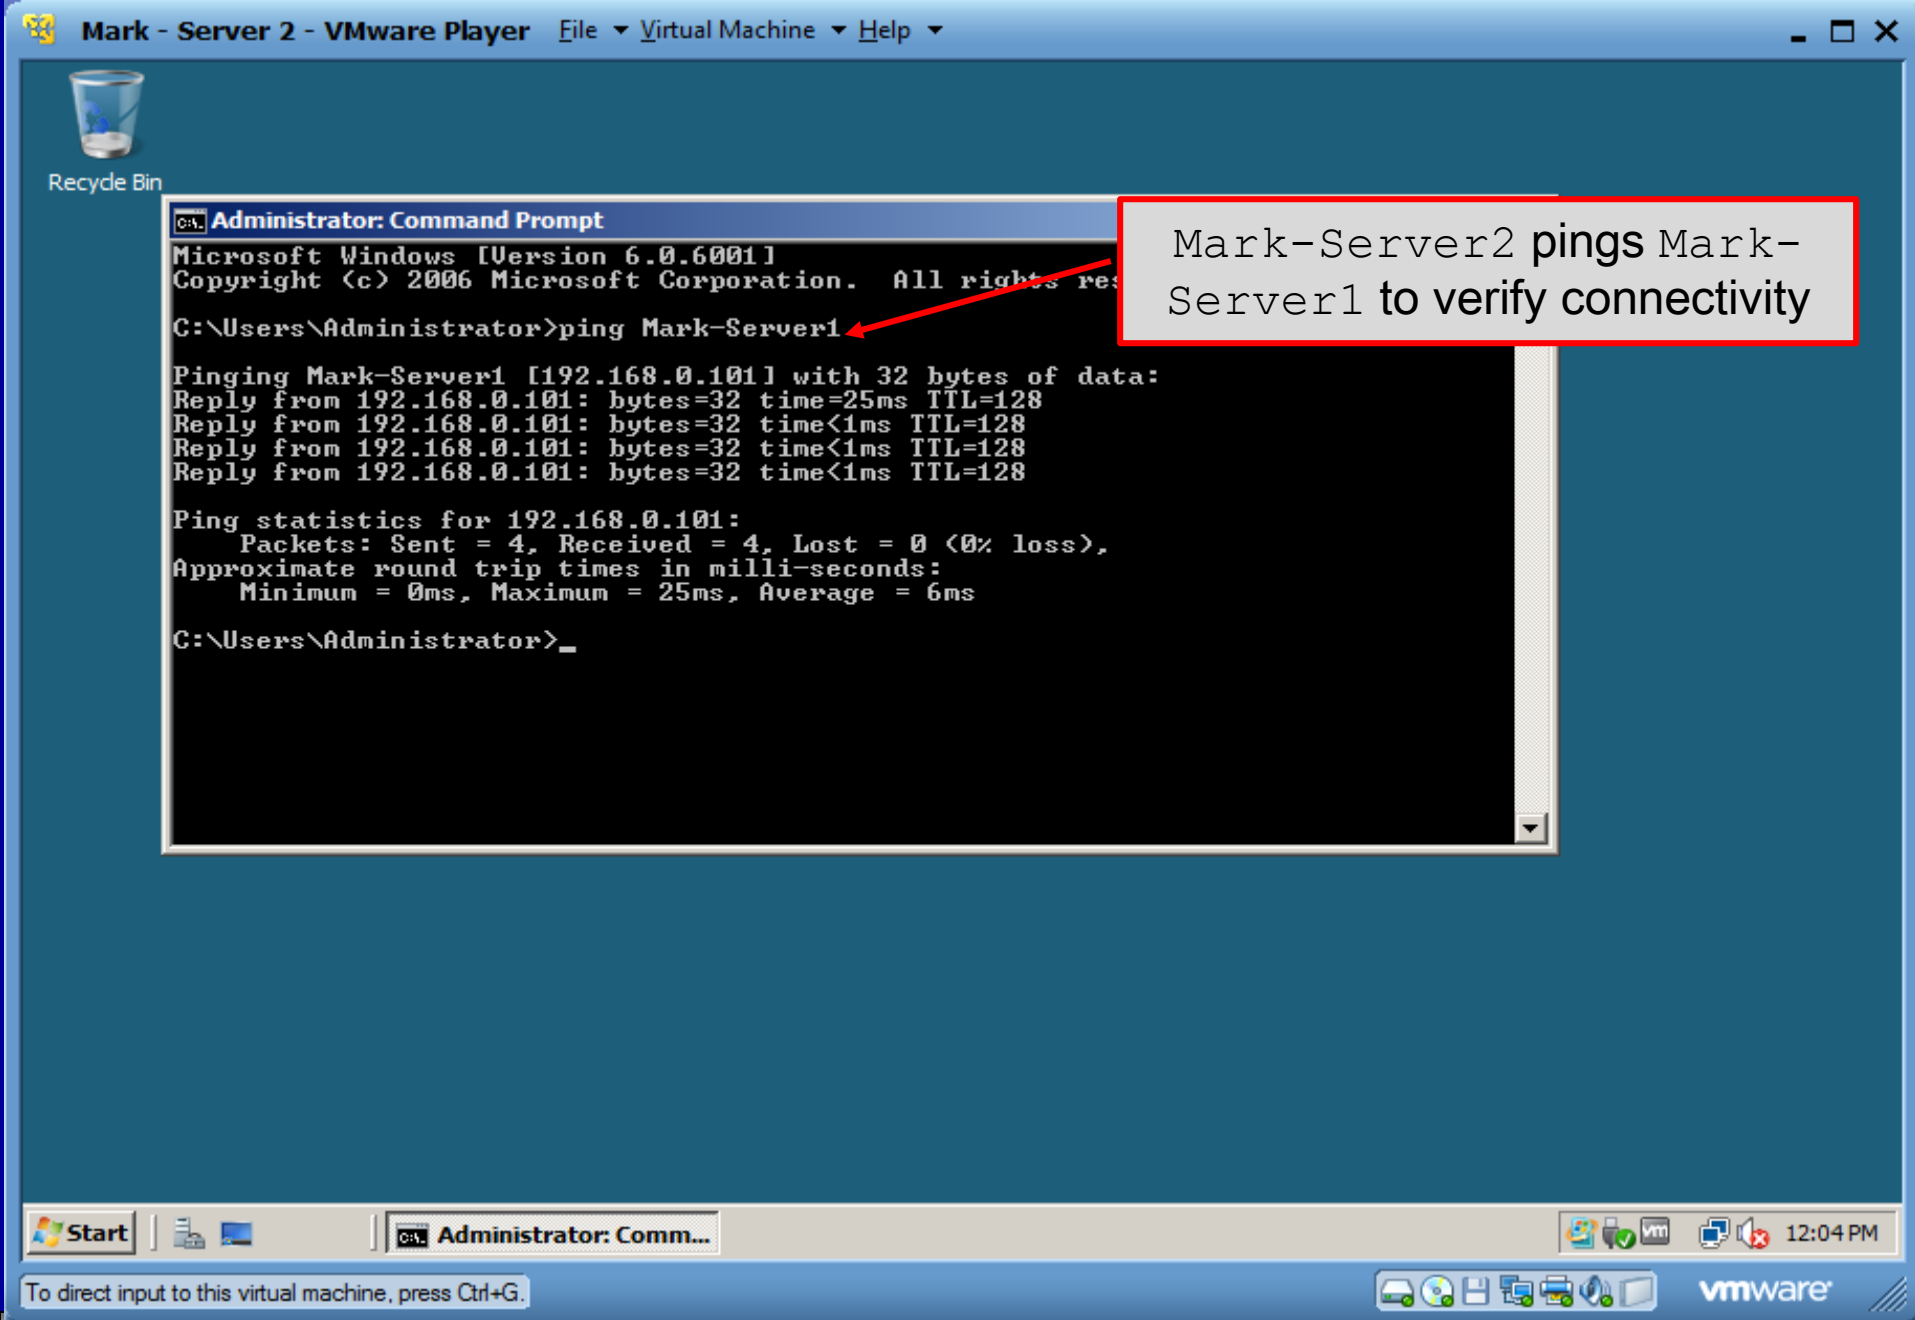

- For a VM to access the network resources of the `savn.local` domain, the VM must be a member of the domain.
- This process is called **joining a domain**.
- In this part of the project you will contact the domain controller (Mark-Server1) from a VM and request to become a member of the domain.
- The actual process of joining a domain varies somewhat from operating system to operating system, so you will see some differences between the actions when Mark-Server2 and Mark-Client1 join the domain, but in both cases you will use the Computer Name/Domain Changes dialog box to accomplish the join.
- The actual process is quite simple and should take you far less time than Project Four required.

Joining A Domain – Mark-Server2

- To begin the process of joining Mark-Server2 to the `savn.local` network, start both Mark-Server1 and Mark-Server2 running.
- From a command prompt, have Mark-Server2 ping Mark-Server1 to verify connectivity.

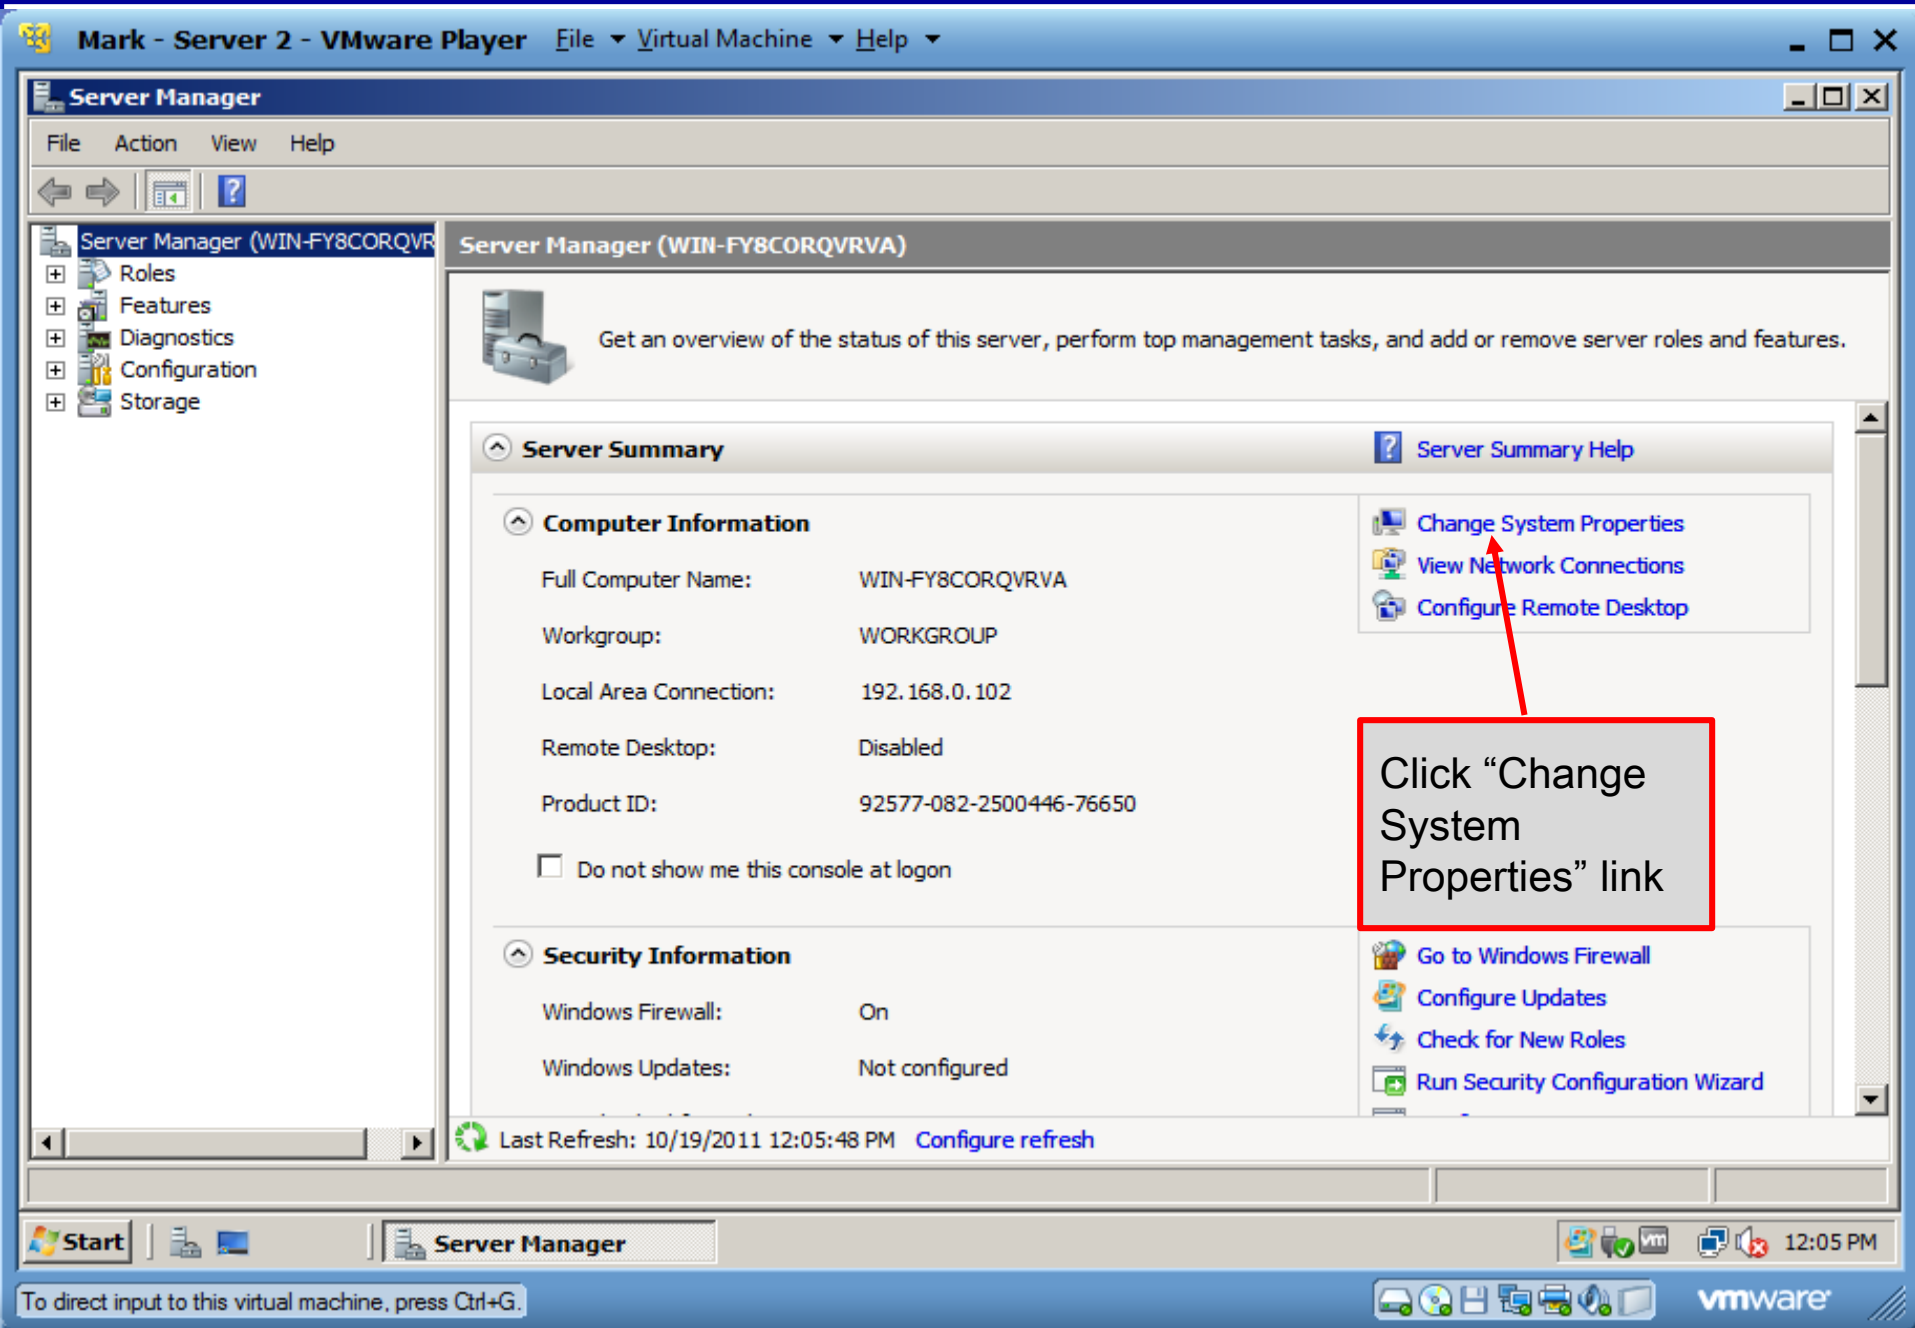

Joining A Domain – Mark-Server2

- From the Start menu in Mark-Server2, click on Administrative Tools, then click the link for Server Manager.
- You should see the window as shown on the next page.

 1:54 PM

Joining A Domain – Mark-Client1

- The procedure for getting the Vista-based Mark-Client1 to join the savn.local domain is essentially the same as that of the Server2008-based Mark-Server2.
- Before proceeding, open a Command Prompt in Mark-Client1 and verify that Mark-Server1 is accessible by pinging the server, as shown on the next page.

Joining A Domain – Mark-Client1

- To connect Mark-Client1 to the savn.local domain, click Start, right click Computer, then click Properties, and then click Advanced System Settings.
- This will open the System Properties dialog box as shown on the next page.

Project Five

- The deliverables for this project consists of six screen shots as shown on pages 35, 36, 39, 51, 63, and 64 respectively.
- For those of you having memory issues as related to the virtual machines, you will need to have a maximum of two virtual machines running simultaneously for this project.
